Energy surfaces for the N^+-N , NO^+-NO , and $N_2^+-N_2$ transitions in a quantum dipole moment potential are computed. The potential is formulated by a linear combination of three diabatic Gaussian basis functions in a valence bond configuration space. The potential describes the dependence on the nuclei of the eigenstate properties. The electron-nucleus dependence is described by means of a set of B-spline functions. The six intrinsic coordinates of the system (three distances and three angles) are expressed as independent diabatic pairs. The potential energies are computed as an expansion in the coupling constant of the quadratic potential, and the coupling constants are determined by matrix diagonalization. The computed energies are accurate to better than 0.1 cm^{-1} , and agree well with the experimental and other theoretical energies. 0.41 and $Q_{\sim A}$ of 0.092 , as expected for a $Q_{\sim B}/Q_{\sim A}$ ratio of 3.43 . The free energy difference was $13.6 \pm 1.7 \text{ kJ mol}^{-1}$. The absorption cross-sections of both the xanthophyll cycle pigments were calculated using the energy gap between the ground state and the 1^{st} singlet excited state of 0.19 eV ($\lambda_{\text{ex}} = 465 \text{ nm}$). Values of $0.88 \pm 0.06 \mu\text{m}^2$ and 0.63 ± 0.04 ◆
